Authors’ contributions

This work was carried out in collaboration between all authors. Author HMF designed the study, wrote the protocol, managed the literature searches and wrote the first draft of the manuscript. Authors HEK and AMEH guided the team work. Author HMO managed the histopathological study. All authors read and approved the final manuscript.

Original Research Article

ABSTRACT

**Aim:** This study aims to evaluate the toxic effect of *Tinospora bakis* roots on body weight, hematology, biochemistry and histopathology on rats.

**Methodology:** Twenty four male Wistar albino rats were divided into four groups, each of 6. For sub chronic toxicity, the aqueous extract was administered orally at a dose of 50, 500 and 2000 mg/ kg -for four weeks- to group 2, 3 and 4, respectively whereas Group 1 was kept as a control. Clinical signs and mortality were observed daily. The weights of the animals were recorded weekly. Blood samples were collected for hematology and biochemistry analysis. Specimens of liver and kidney were kept in 10% formalin for histopathology.

**Results:** The results revealed that all animals in the four groups survived, and no mortality was recorded. The body weights of the animals increased in group 2 and 3, decreased in group 4. The extract had no adverse effects on hematology, biochemistry and histology of rats at doses of 50

*Corresponding author: E-mail: hayatmahgoub@yahoo.com;
and 500 mg/kg, but caused significant alteration at dose 2000 mg/kg. White blood cells (WBCs) were significantly (P<0.05) increased; Red blood cells (RBCs), Hemoglobin (Hb) and Packed cell volume (PCV) were significantly (P<0.05) decreased. Total protein and albumin were significantly (P< 0.05) decreased whereas Urea, creatinine, Alanin Transaminase (ALT), Asparate Transaminase (AST) and Alkaline phosphatase were significantly elevated. These findings correlated with histopathological changes on liver and kidney.

**Conclusion:** The low doses of *T. bakis* aqueous extract were not toxic, but the high dose cause hepato-renal toxicity.

**Keywords:** *Tinospora bakis*; aqueous extract; toxicity; rats.

**1. INTRODUCTION**

*Tinospora bakis* (A.Rich) Miers in Hook. Niger. Fl.: 215 (1849) belongs to the family Menisperaceae. It is known in Sudan as Irg al-hagar. It is found at low plains and distributed in West and Central Africa [1].

Many plants contain chemical constituents which are used for different medical purposes. However, over dosage of plant products containing medical compounds may cause toxic effects when introduced into the body [2]. The toxic phytochemicals produced by plants include alkaloids, sulphur, phenol, tannin, proteins and enzyme inhibitors [3]. Toxins have direct and indirect mechanisms of actions on the target organs (liver, kidney, brain, lung and intestine). The mechanisms of actions include direct and indirect damage of tissue, effect on function and genetic defect [4].

In view of the various medical uses and pharmaceutical results of *Tinospora bakis*, preliminary screening of the plant for in vivo toxicity is needed. Palantine isoquinoline alkaloid was isolated from the plant [5]. The woody part of the root of *Tinospora bakis* (A. Rich) Miers has a high character in West Africa as a diuretic and febrifuge [6]. In addition, the root is used against jaundice, hematuria, bilious fever and yellow fever, malaria and schistosomiasis. Externally, the decoction is applied against various skin problems. The leaves are similarly used as diuretic and tonic. The aqueous extract of the root containing the alkaloid fraction showed moderate activity against *Plasmodium falciparum* [7]. Syrup of the aqueous root extract induced a significant increase of the biliary secretion in rats [8]. Columbine, in small doses, was found to increase the bile, stomach and intestine secretion; in high doses it produced greasy degeneration of the liver. Palasmine showed a stronger antipyretic effect in rabbits [9]. A lyophilized aqueous extract of *T. bakis* at concentration of 1-4 mg/ml showed in vitro hepato-protective activity after treatment with CCl4 [10]. In mice, the aqueous extract of the root administered either intra peritoneal or subcutaneously showed LD50 of 360 and 425 mg/kg, respectively.

On the other hand, intra peritoneal administration of *T. bakis* methanolic extract to rats at a dose of 100 mg/kg was toxic [11]. *In vitro* study of the plant caused cytotoxicity on lymphoblast cells at concentration of 10 mg/ml [12].

Other species of *Tinospora*, such as *T. tomentosa* aqueous and methanolic extracts were found to be non toxic in mice and rats at doses up to 3.5 g/kg [13]. *Tinospora rumphi* is a folkloric medicinal plant that is widely distributed in Asia and Africa. It has been used to treat many diseases including jaundice which is a manifestation of liver damage [14].

*Tinospora bakis*, *T. cordifolia*, *T. crispa*, *T. sinensis*, *T. smilacina*, and *T. sagittata* have been reported to possess significant immunomodulatory effect [15].

In Sudan, the macerated roots of *T. bakis* are used for headache in folk medicine [4]. The plant extract investigated against *Plasmodium falciparum* [16], *Madurella mycetomatis* [17]. Furthermore, *T. bakis* was evaluated for trypanocidal [11], antihelierial [12] and antidiabetic activity [18].

The objective of plant toxicity test is to clarify the toxic effects of the plant. The toxicity of *T. bakis* roots extract is necessary since this has not been previously done in depth.

**2. MATERIALS AND METHODS**

**2.1 Plant Collection**

The roots of *T. Bakis* were collected from Ingassana hill in East- south of The Sudan. The
plant was identified and authenticated by a botanist at the Medicinal and Aromatic Plants Research Institute, Khartoum, Sudan. The voucher specimen has been deposited in the herbarium museum of the Institute. The plant air-dried in the shade, coarsely powdered and kept in polythene bags at room temperature.

2.2 Animals

Clinically normal, twenty four male Wistar albino rats, 4-5 weeks of age, weighing (114-117 g) were brought from the Medicinal and Aromatic Plants Research Institute, Khartoum, Sudan. The animals were kept in metal cages to adapt for one week. The rats were fed with a standard diet which is manufactured commercially for poultry (Layers). Feed and water were provided *ad libitum*. This work was carried out according to the international regulations for the use of laboratory animals. Principles of laboratory animal care” (NIH Publication No. 85-23, revised 1985) were followed, as well as national laws were applicable.

2.3 Preparation of Plant Extract

The plant extract was prepared as described previously [19]. Hot distilled water (500 ml) was added to 100 g of the coarsely powdered plant roots and left to cool down with continuous stirring at room temperature. The extract was then filtered through Whatman No. 1 filter paper, and then transferred to the freeze-dryer (Trivac, U.S.A.). The yield percentage of the extract was 7.89%.

The required weight of the extract for each group was calculated according to the dose, dissolved in 6 ml of distilled water.

2.4 Experimental Designs

Twenty four male Wistar albino rats were divided into four groups, each of 6 rats. Group 2, 3 and 4 were used for testing of sub chronic toxicity, and group 1 was kept as a control. The extract was given at one of the fixed dose level (50, 500 and 2000 mg/kg) as low, intermediate and high level.

2.4.1 Screening of the aqueous extract of *T. bakis* roots for toxicity

The volume of the extract given to each animal based on the body weight. The aqueous extract of the plant was administered orally to the rats in group 1, 2 and 3 at doses of 50, 500 and 2000 mg/ kg/ day, respectively for four weeks; keeping group 1 as a control.

Clinical signs of toxicity and/or mortality were observed daily. The weights of the rats were recorded at the day of dosing, at weekly intervals thereafter, and at the time of death or when the animals were euthanized.

2.5 Blood Collection for Hematological and Biochemical Analysis

Blood samples were collected weekly-starting from week zero (Control) - from the orbital sinus of rat’s eye - in Ethylene Diamine Tetra acetic acid (EDTA) and plain vacutainers, for hematological and biochemical tests, respectively. Sysmex Haematology System KN-21N(Germany and Sysmex Biochemistry System / Germany) instruments were used for analysis. The procedures were carried out as described in the manual of the automated machines.

2.6 Pathological Examination

Rats in group 1, 2, 3 and 4 were euthanized at the end of the experiment. Specimens of normal and abnormal liver and kidney were fixed in 10% neutral buffered formalin and processed for histopathological examination.

2.7 Statistical Analysis

The data collected during the study were analyzed using the computer program SPSS version 20. The statistical analysis was done using One Way ANOVA, followed by Duncan multiple comparison test. The data are expressed as mean ±SD. The results with P<0.05 were considered significant.

3. RESULTS

3.1 Effect of the Extract on Mortality and Body Weight

There was no mortality recorded even at the highest dose (2000 mg/kg) after oral administration of the extract.

The aqueous extract of *T. bakis* roots was well tolerated by the animals after oral administration of the doses 50, 500 and 2000 mg/ kg to group 2, 3 and 4, respectively.

The effect of the extract on body weights of rats was shown (Fig. 1). The extract significantly (P<0.05) increased the bodyweights of rats in group 1, 2 and 3; decreased in group 4.
3.2 Effect of the Extract on Hematological and Biochemical Parameters

The plant extract altered the haematology and biochemistry of rats in group 4 only. The haematological changes on blood of rats administered orally aqueous extract of *T. bakis* were summarized (Table 1). WBCs, RBCs, Hb and PCV were not affected in group 2 and 3, but significantly (P<0.05) changed in group 4.

The toxicological effects of the extract on the biochemical parameters were presented (Table 2). Oral administration of the aqueous extract at doses of 50 mg/ kg and 500 mg/ kg had no effect. However, the dose of 2000 mg/ kg was significantly (P< 0.05) altered all the parameters.

Table 1. Hematological changes on the blood of rats given aqueous extract of *Tinospora bakis*

The data expressed as Mean ± SD, *P < 0.05 is significantly different from the control, n=6
3.3 Histopathological Changes

Necropsy of rats in group 1, 2, 3 showed normal livers and kidneys. Though, the extract caused histopathological changes in liver and kidney (Group 4). The liver characterized by vesicular nuclei and accumulation of cytoplasm at the boundaries of hepatocytes (Fig. 2B), compared with the control (Fig. 2A). The kidney revealed dilated and segmented glomerular tuft (Fig. 3B) referring to the control (Fig. 3A).

4. DISCUSSION

There were no changes on the animals’ behavior and/or mortality recorded after oral administration of repeated doses at 50, 500 and 2000 mg/ kg of the aqueous extract of *T. bakis* roots. This result in agreement with the findings mentioned that different doses of the extract were not fatal up to a dose of 2000 mg/ kg [18]. On the other hand, the dose 2000 mg/ kg was toxic but not fatal. This result disagree with previous study reported that the aqueous and methanolic extracts of *T. tomentosa* were found to be non toxic in mice and rats at doses up to 3.5 g/ kg [9]. The variation could be to the different plant species.

Body weight changes may reflect the general health status of animals [20]. In the current work, the body weight gain in group 2 and 3 suggest that the extract did not interfere with the normal body metabolism of the animal as the increment in food and water intake is synonymous to an increase in body weight. This indicates that the extract of *T. bakis* did not have general toxic effects and influence on animal food intake at doses of 50 and 500 mg/ kg. The findings were

---

**Fig. 2.** Section of rat liver: (A) Normal control (group 1). (B) After oral administration of aqueous extract of *T. bakis* at a dose of 2000 mg/ kg (group 4) showed vesicular nuclei (white arrows) and accumulation of cytoplasm at the boundaries of hepatocytes (black arrows), H&E (× 40)

**Fig. 3.** Section of rat kidney: (A) Normal control (group 1). (B) Dosing of 2000 mg/ kg aqueous extract of *T. bakis* (group 4) dilated and segmented glomerular tuft (back arrow), H&E (×40)
supported by previous results in which the aqueous extract of the plant improved the body weight of diabetic rats at a dose of 400 mg/kg/day [18]. However, decrease in bodyweight (group 4) indicated abnormality or toxicity which influenced food consumption and metabolism.

The assessment of blood hematology and clinical biochemistry provides an insight to possible damage caused by the extract in the hepatic and renal functions. In toxicity studies, evaluation of liver and kidney functions is germane because both organs are essential for the survival of an organism [21]. Hematological and biochemical changes are indicators of toxicities [22]. The doses of 50 and 500 mg/kg had no toxic effects on both parameters as well as the histological findings. This finding disagree with previous result exhibited that intra peritoneal administration of T. bakis methanolic extract to rats at a dose of 100 mg/kg was toxic; causing decrease in hematological values and an increase in serum enzymes [11]. This could be due to the variation in the solvent used and the route of administration.

Increase of WBCs in group 4 could be attributed to the combined effects of physiological and chemical factors in the metabolic system of animals [23]. The mechanism of action of WBCs and its component are defensive against foreign substances. The alteration in RBCs and Hb may be due to defective hemopoiesis inhibited erythropoiesis or increase in destruction of red blood cells [24,25] which could cause anaemia.

The biochemical changes are biomarker of abnormality or toxicity. Evaluation of total protein gives an estimation of the nutritional status and diagnostic measurement of liver and kidney diseases [26]. Reduction in total protein and albumin is an indicator of impaired hepato cellular function [27]. The observed increase (P<0.05) of serum urea and creatinine in group 4 suggest renal malfunction [28]. Transaminases (ALT and AST) and Alkaline phosphatase are sensitive enzymes used to assess the severity of liver damage [29]. Primary and secondary hepatic diseases can cause elevation of both ALT and AST [30]. The increment in the activities of transaminases indicates that the plant may induce hepatic parenchyma injury, hepatic dysfunction and leakage of these enzymes from liver cytosol to the blood stream [31,32]. Overall, the biochemical changes were correlated with the histopathological findings on the liver and kidney.

5. CONCLUSION

The results revealed that the low doses of the aqueous extract of T. bakis roots were not toxic, but the highest dose may cause hepato renal toxicity. Further research is recommended for isolation, structural determination and identification of the toxic compounds; and the mode of action of the plant T. bakis.

CONSENT

It is not applicable.

ETHICAL APPROVAL

All authors hereby declare that “Principles of laboratory animal care” (NIH Publication No. 85-23, revised 1985) were followed, as well as national laws were applicable. The protocol for the use of laboratory animals in this study was approved by the Ethical Approval No. EA /0019/2018, The Sudan Veterinary Council, Ministry of Cabinet, Republic of The Sudan.

ACKNOWLEDGEMENTS

The authors acknowledged Central Veterinary Research laboratory for permission to publish this article. Our thanks extended to Dr. Hala Elrayah at the Department of Biochemistry, Nutrition, Toxicology and Pharmacology for performance of statistical analysis.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
